cache mapping technique

CPU searches data in the cache,

Tritially eache memory is empty, so the brequently accessed data has to be loaded into cache memory

2) eache consider cache is full and new data has to be loaded into cache.

To load xory one of data item in the cache has to removed, to make a space for new data.

In the above two Situations, one has to decide.

which data block of main memory is to be loaded in which block of the cache?

Different mapping techniques will help to manage mapping of data from main memory to cache memory. i) Direct mapped cache.

A simple way to determine cache locations in which to stone memory blocks is the direct-mapping technique

In this

Block j of the maps to -> Block j of, fotol no g
m. m

blocks in cache

Eg. consider a couche with 128 blocks of 16 words

each
I tacke block zan hold 16 words

and we have a m.m with 2018

words & no of bite in m.mis16

i-e 1 Blocko

Addreu 0000 0000 0000 0000

Block 4095 1111 1111 1111

main memory totaly has 64 k words (total capacity)

X = 1024, each location capacity is 16 words

value.

64 × 1024 words

16

= 4096 locations i.e from
0 to 4095

placement of a block in the cache is determined by m. M. CRIP general Given m.m address is now divided into 3 parts 1) word 2) Block 3) Tag bit

Block word

word : - Total no quonds in a location i e 16 24=16 so 4 bits ig

ter wood

Block! - Totally we have 128 blocks in the cache i e 27 = 128 : 7 bits too block.

Tag: - Remaining (16 - (4+7)) = 5 bits is for tag

These bits are used to identify whether data is present
in cachelnot. 8: - Block 3 g m.m is stoned in

3 1/128 = 3 g the cache blow.

Block 256 & g the m.m is a mapped to 256 / 128 = 0 oth block of the cache

Blow 1, 129,257 are stoned in cache blows

1 / 128 = 1 } 15+ block of the cache

257/, 128 21 Since more than one m. m block is mapped contra given cache block position contention arises.

Associative mapping

- 1) In this main memory block can be placed into any cache block position.
- v) Space in the cache can be utilized more efficiently
- 3) It the cache is full, new data to be loaded then to remove one of the cache block, least succently page suplacement algorithm is used
- 4) cost q associative cache is higher than the cost of direct mapped cache.

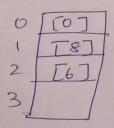

Ego 5) main memory address is divided into two fields Tag word ! - 4 bits word

since 24=16 words Tag: Remains bite core tag bit

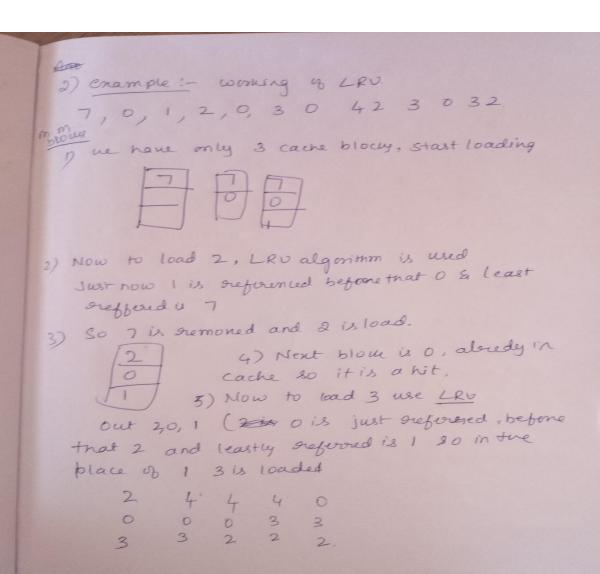

Simple enample

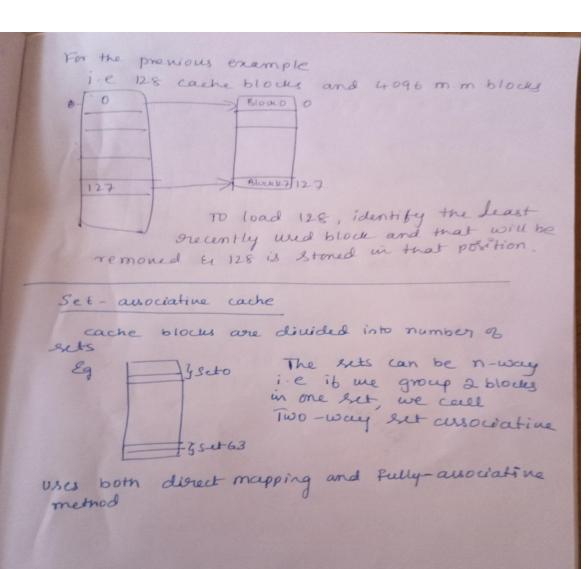

consider cpv has suggested the data present in the main memory of 0, 8, 0, 6,8

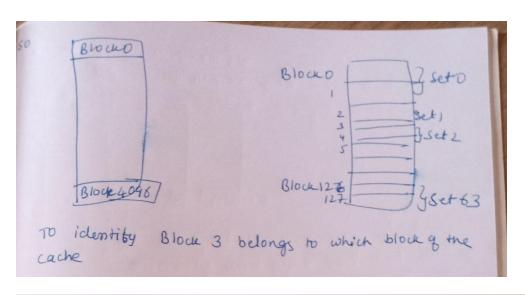

and we have four blows in the cache

- 1) on blow of m. misloaded in on a cache
- 2) 8 g m.m =>1 g cache
- 3) 0 -> nit
- 4) 6 mm => 2nd block &
- 5) 8th -> hit

Set-associative

Blow

A block set-associative cache consister a a total of 64 blocks divided into 4-block sets. The main memory consists of 4096 blocks, each consisting of 128 words

a) How many bits are there in a main memory

Blocko

- b) How many bit we there in each of the TAG. SET and word fields?
- a) Total no q blocks in m.m = 4096

 Each block holds = 128 words

 The capacity 4 m.m = 4096 ×128

 = 524, 288

 2 = 524, 288
 - 19 bite is some in m.maddress
- TAY !- Remaining 8 bit is too tag

 SET !- 64 blocks / 4 = 16 = 7 4 bit

 word! 128 words (27) so 7 bite

8	4	7
TAG	Set	word

problems on cache memory

- of addressable locations and a 32 kilobyte desect mapped cache with 8 bytes per block. The minimum addressable unit is a byte.
 - a) How many blocks are in the cache?
 - D) Show how the memory address is partitioned?
- a) The main memory has 16 megabytes

So the total no q bits in main memory

address = 24 bits

Cache has 8 8 8.

32 kB

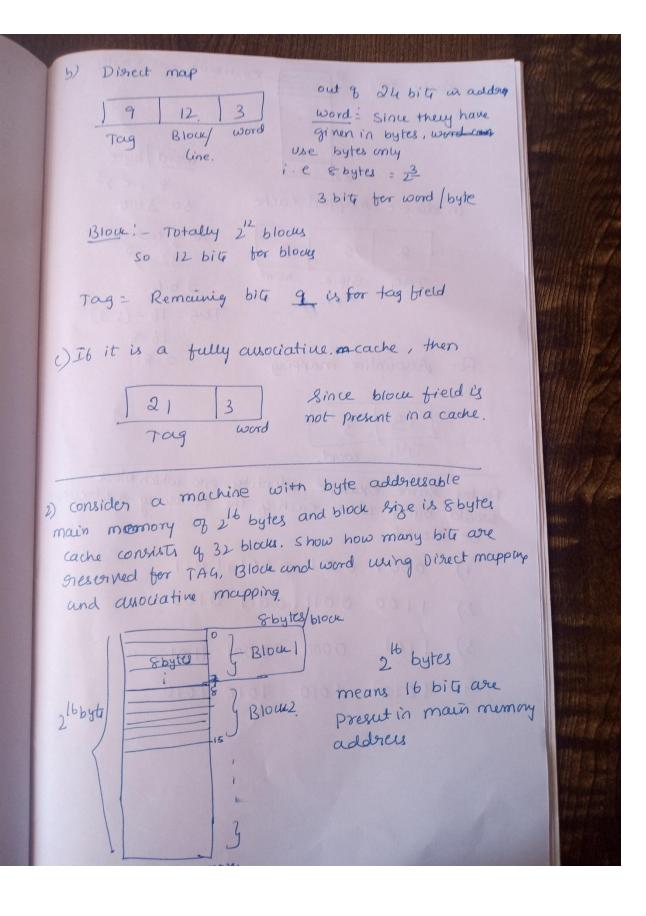

32 kB

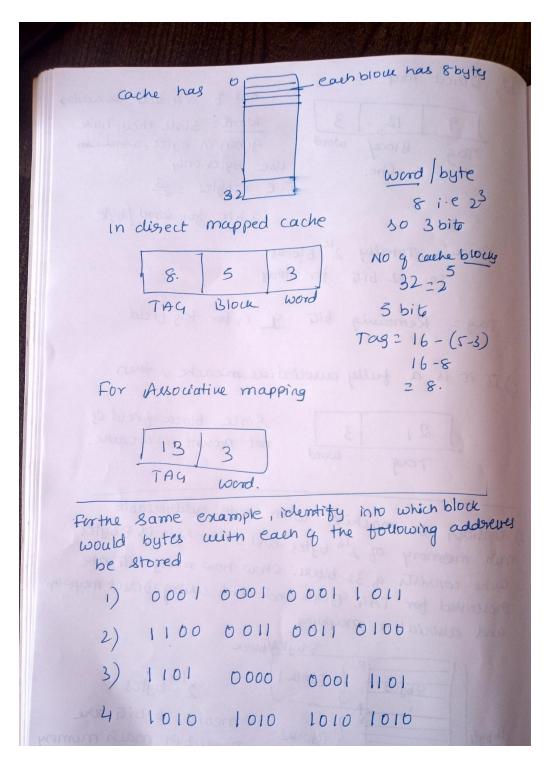

32 x 102 y

8

2 x 2 = 212

2 cache blocks

Answer:

- 1) 3 2) 6
- 3) 3 4) 21
